Tackling security issues in virtualization

© Kurzgesagt

About me: Olivier Lambert

- <u>Vates</u> CEO/co-founder
- Former sysadmin
- Xen user (since 2006)
- <u>Xen Orchestra</u> (2013)
- <u>XCP-ng</u>, a Citrix XenServer fork (2018)
 - now hosted in Xen Project (Linux Foundation)!

Slides available at <u>https://vates.fr/pts</u>

Virtualization, still everywhere?

I've heard:

- "It's a thing from the past" (IBM S/360 to be fair)
- "Everybody is in the Cloud"
- Magic words: "Kubernetes", "Serverless", "SaaS/PaaS/IaaS"

This is a good sign.

It means virtualization is ubiquitous.

Also meaning we'll face new challenges.

New challenges?

- > "Whole stack" security awareness *****
- > Specific CPU security mitigations *science*
- > Security in new virtualization use cases ())

Whole stack security in question

We forgot "layer 1"

Years of trends further away from the metal:

- 1. Virtualization
- 2. First public cloud
- 3. Virt. orchestration (PaaS/IaaS)
- 4. Containers
- 5. Container orchestration (k8s)
- 6. Serverless
- 7. <u>#Developerless</u> ("No-code")

What's next?

Whole stack security in question

In the mean time...

A big shift for hardware vendors, software is growing in their offer:

- more firmware
- BMCs with more features (Baseboard Management Controller)

From teams with other priorities than security.

CPU vulnerabilities

Right in the silicon, due to branchprediction leak and injection:

- <u>Meltdown</u>
- <u>Spectre</u>
- <u>Foreshadow</u>
- <u>ZombieLoad</u>
- <u>CacheOut</u>
- <u>LVI</u>

And all their respective variants.

IPMI/BMC vulnerabilities

Extra chip with its own CPU/net, allowing:

- power cycle
- update firmware
- mount virtual devices
- UEFI changes...

Vulnerabilities found:

- escalation of privilege
- denial of service
- information disclosure

IPMI Block Diagram

So what?

We "realized" that:

- "Low-level" software must be updated often (microcode, firmware, BMCs)
- We might disable HT and/or enable mitigations that can hurt perfs
- Side channels and hardware bugs are here to stay
- Security as a whole: "all layers" matters

What's the impact on virtualization?

Security as a whole

What about security and perf together?

- Mitigations cost is high (SMT/HT disabled, etc.)
- Perf/risk ratio (leave the choice)
- Keep virt overhead low

Compute side

- Rethink/refactor parts of hypervisor regarding:
 - CPUs isolation/sec features (SME/SEV,SGX)
 - "Think big" for massive CPUs (EPYC Rome, NUMA impact...)
 - How to expose this complexity to the end user?

New use cases

- Embedded world
 - Eg: Automotive projects, Aerospace, etc.
 - Compliance and security challenge
- Edge computing: survive in hostile environment ("on the field")
- New architectures (RISC-V, Power9)
- More ARM deployments (eg: Graviton 2)

Security challenges for virtualization

3 ways to face these security challenges:

- 1. Technical solutions
- 2. Organizational solutions
- 3. Integration solutions

Technical solutions: flexibility and painless updates

- Modularize the code:
 - mitigations enabled or not
 - $\circ~$ extra features or not
 - stripped down version for maximum security (eg: OpenXT, QubeOS)
 - allow a full spectrum of security/perf
 - guide people (document it!)
- Easier updates means more security:
 - \circ apply μ code updates without reboots (*late \muCode loading* in Xen)
 - hypervisor live patching
 - <u>hypervisor live upgrade</u>

Technical solutions: R&D

- More research efforts, new ideas:
 - branch hardening
 - <u>core scheduling</u> (avoid side channel attacks)
 - better isolation
 - <u>disaggregation</u>
 - <u>secret-free hypervisor</u> (no global stack, no direct map...)
 - use latest hardware sec features

Organizational: process improvements

React fast, and adapt to cope with unpredictable vulnerabilities:

- A solid security workflow (eg <u>Xen Security Process</u>)
- Using community superpowers:
 - meetings/summit with devs
 - discuss with people on the field (end-users)
 - exchange with similar projects (eg KVM/Xen/Linux kernel)
 - include "external people" (eg coming from sec world)

Integration is key

Building an integrated product matters:

- Federate projects
 - community & ecosystem organizational solution
- Secure by default
 - o default platform choice but flexible
 o easy config/painless updates
- Strong R&D focus on sec & perf
 - find new technical solutionsdeliver them "turnkey"

Integration example

<u>XCP-ng</u>:

- Xen distro working "out-of-the-box"
- Bundled with various projects (Xen/Linux/OVS...)
- Powerful API (compute/net/storage)
- Fully Open Source

Xen Orchestra:

- Web/CLI capable tool to manage XCP-ng
- Expose sec options but also backup etc

Our work

- Community
 - Build bridges between various communities (devs/end-users)
 - Federating various projects (inside/outside)
- Secure by default
 - Full distro control to make choices
 - $\circ~$ Exposing features in GUI
- Intense R&D
 - $\circ~$ guest and host secure boot
 - compute/net/storage perfs
 - exploring other arch

Conclusion

Virtualization will:

- see more challenges than ever (security and complexity on physical layer)
- need to keep the pace, requiring large collaborations AND research efforts
- still be relevant as long as the overhead is contained
- deliver integrated solutions to face those challenges
- see a new cycle of trends
 - innovation and competitors will push in the CPUs/hardware/low-level software
 - great opportunities for virt projects by working on hardware/software interface
